Figure 1: Reframing Wizard-of-Oz for proxy-mediated interaction. Traditional WoZ assumes dyadic system simulation, whereas proxy-mediated interaction introduces a triadic structure for designing and evaluating proxy system.

Abstract

Wizard-of-Oz (WoZ) is a widely used method for prototyping interactive systems in which a human wizard simulates a system's behavior. As AI increasingly functions as a personalized proxy representing individuals' behaviors, identities, and relational norms, the wizard's role shifts from a neutral system operator to an identity performer acting on behalf of a specific user. In this paper, we reframe WoZ methods for proxy-mediated interactions by introducing a triadic structure consisting of the represented user (*Source*), the system wizard (*Proxy*), and the system user (*Partner*). From this structure, we derive three methodological implications for WoZ in proxy-mediated interaction settings: (1) reconceptualizing the wizard's role as a proxy representative, (2) redefining evaluation criteria to account for the proxy's delegated interaction, and (3) recognizing the social and ethical implications of proxy-mediated interaction.

1 INTRODUCTION

Recent advances in generative artificial intelligence, large language models, and multimodal synthesis systems have enabled computational agents to simulate personal aspects of specific individuals, including their linguistic style, physical traits, behavioral patterns, and decision-making [16, 17, 23]. Unlike traditional intelligent assistants designed to be generic and task-oriented, these emerging systems can operate as personalized social proxies that engage in interpersonal interactions while maintaining social presence for a particular user. As these proxies can autonomously perform social and task-oriented works on behalf of users, such delegation has been proposed for applications including teaching and classroom support [11], multitasking in teamwork [3], distant family communication [21], automated survey and interview [11] and remote meeting for individuals with limited availability or bandwidth [15].

Despite growing interest in proxy delegation and the technical capability of AI systems to imitate individual communication styles and behavioral patterns, the evaluation of these methodologies remains underexplored. A proxy agent is not judged only by whether its responses are fluent or correct, but by whether others treat its actions as an appropriate representative for the source person in a given situation. Yet, the existing research lacks standardized experimental and design methodologies for evaluating whether an agent meaningfully enacts proxy interaction, in which third parties recognize, accept, and respond to the agent as a legitimate proxy of the represented individual. This challenge is especially salient

in delegated interactions, where the agent's behavior shapes not only task outcomes but also interpersonal and relational aspects of interactions, influencing trust and system accountability.

To address this gap, we propose reframing the Wizard-of-Oz (WoZ) methodology as a design and evaluation method specifically for proxy agents. Traditionally, WoZ refers to experimental setups in which a hidden human operator—referred to as "wizard"—covertly simulates system intelligence in order to prototype interactions when automation is incomplete or infeasible [4, 9]. For proxy agents, however, the wizard's role extends beyond generating system outputs, as it enables designers to explore what constitutes socially acceptable representation before determining what can be generated. The human wizard needs to perform an embodied, relational enactment of proxyhood, not only producing responses consistent with the source but also managing boundaries, delegation norms, accountability, and social expectations that arise when acting on someone's behalf. Under this framing, wizarding becomes a method for probing what proxy behavior should be beyond what it can sound like.

This study examines how we design and evaluate whether an agent can successfully perform proxy interaction. We conceptualize proxy-mediated interaction between two human roles: the *source*, whose interaction is delegated to the proxy agent, and the *partner*, who interacts with the proxy as an audience and collaborator [16]. By observing how sources articulate delegation strategies and how partners interpret and respond to proxy behavior, this method enables researchers to examine collaborative dynamics, social adoption, and representational legitimacy as design variables. Through this reframing, we outline methodological considerations for the early-stage design and evaluation of proxy agents in human-centered contexts, contributing to the design and practice of future research on proxy-mediated interaction.

2 BACKGROUND AND RELATED WORK

2.1 Wizard-of-Oz Methodology in HCI

Wizard-of-Oz (WoZ) methods are widely used in HCI to prototype intelligent systems prior to full automation. In a typical WoZ setup, a hidden human operator (wizard) simulates system behavior while participants believe the system is autonomous [19]. WoZ emerged from early work in natural language interfaces, conversational systems, and robotics, enabling researchers to explore interaction design before technical capabilities were fully realized [19, 25]. Traditional WoZ workflows emphasize defining a system's behavioral scope in advance, executing responses through scripts or graphical control interfaces, and logging interactions to inform later automation [1, 22]. Performance is commonly evaluated using metrics such as task completion, response latency, and perceived naturalness [20]. Within this framing, the wizard is expected to act as a neutral executor, maintaining consistency and invisibility throughout the interaction [18]. However, recent studies highlight substantial gaps between this idealized view and actual practice. Wizards often perform cognitively and socially demanding labor, including anticipating user behavior, managing complex interfaces, and maintaining believable timing under pressure [1]. In addition, wizarding involves emotional and ethical work, such as discomfort with deception and the burden of simulating empathy or warmth through

mediated systems [7]. These challenges suggest that WoZ is not merely a technical scaffold, but a socially performative role, particularly relevant when systems engage with identity, representation, or social presence.

2.2 Proxy-Mediated Interaction

A proxy is an entity that acts or communicates on behalf of a person, representing their presence, intent, or identity within an interaction. In human-computer interaction, proxy-mediated interaction refers to situations in which a technological system mediates or substitutes for a human source in social or task-oriented contexts [16]. Unlike conventional tools that merely assist users in performing actions, proxy systems participate directly in interaction as delegated representatives, shaping how the user's intentions and identity are conveyed to others.

Prior work on AI-mediated communication shows that when systems intervene in message composition, interpretation, or response generation, communication media can shape both the message and the perceived authorship of the sender [10]. When messages are generated or modified by computational systems, recipients may attribute statements to the user, the system, or their collaboration, blurring boundaries of agency and responsibility. As a result, proxy systems introduce interpretive challenges in determining who is accountable for an action and how the represented individual should be understood in interaction.

Proxy agents can take multiple forms depending on how the source is represented in interaction. Some proxies operate through communication systems that mediate or generate messages (e.g., email assistants or conversational agents) [3, 13], while others rely on graphical or embodied representations such as avatars, virtual humans, or telepresence robots that convey aspects of the source's identity through visual appearance, voice, or physical presence [6, 8, 15]. Across these systems, evaluation has typically focused on metrics such as realism, engagement, or perceived naturalness. However, as proxy actions can shape perceptions of the source's identity, intentions, and relational norms, it is important to understand how interaction partners interpret proxy behavior in situated interaction, and how legitimacy and accountability are established when agents act as representatives of individuals.

2.3 Social Interpretation of Source Representation

Recent work explores computational representations of personal identity, such as large language models that simulate aspects of a person's personality, values, or contextual knowledge [14]. These systems enable proxies that represent communicative patterns and decision-making tendencies in addition to stylistic traits. As proxies increasingly act on behalf of users, delegation introduces interpretive challenges for both users and interaction partners. Studies of text-based AI clones raise concerns about authenticity and user control over proxy-generated communication [13], while voice-mediated agents highlight ambiguity in whether statements should be attributed to the user or the system [3]. Embodied proxies attending meetings on a user's behalf further complicate these interpretations by positioning the proxy as a social participant rather than a passive tool [15].

Across these modalities, proxy delegation shifts interaction from direct communication between individuals to mediated representation, where the proxy's actions are interpreted through assumptions about the person it represents. As a result, perceptions of proxy performance often depend less on technical competence than on whether the proxy is treated as a legitimate extension of the source. While prior studies document user experiences in creating or deploying proxies, less attention has been given to how interaction partners interpret proxy behavior in situated interaction, or how legitimacy and accountability are negotiated when computational agents act on behalf of individuals.

3 WIZARD-OF-OZ IN PROXY-MEDIATED INTERACTION

Designing Wizard-of-Oz (WoZ) studies for personalized proxy agents introduces challenges that fundamentally differ from traditional WoZ applications. Traditionally, WoZ methods are organized around a user–system dyad setting where a hidden operator simulates generic system intelligence, and assessed through output quality, usability, or perceived human-likeness. WoZ for proxy-mediated interaction, by contrast, involves a **triadic structure**: (1) a *source* user who delegates representation, (2) a *proxy* who represents the source as a wizard, and (3) a *partner* who interprets and responds to the proxy's interaction (See Figure 1).

This shift of WoZ for proxy-mediated interaction redefines the aim of wizarding from simulating a generic system to enacting specific proxyhood. The wizard is not merely executing predefined functions, but performing a socially accountable representation of a particular person—often under conditions of uncertainty about what aspects of identity matter in a given context. As proxy agents operate within interpersonal relationships, proxy studies evaluate not only whether responses are fluent or correct, but also how their behavior is interpreted and accepted as the appropriate representation of the source. This requires evaluations from both source and partner: whether the partner recognizes the proxy as a legitimate representative and whether the source experiences that representation as aligned with their intent and boundaries.

In this study, we highlight that this reframing has three key implications (Table 1): the wizard's role must be reconceptualized as identity representative rather than system operator (§3.1); evaluation must foreground social legitimacy and relational fidelity rather than generic human-likeness §3.2); and study designs must explicitly address the social and ethical requirements that arise when representing a person through delegation (§3.3).

3.1 Reconceptualizing the Wizard Role

In traditional Wizard-of-Oz (WoZ) studies, the wizard functions as an invisible operator who executes predefined system behavior with minimal personal interpretation. In proxy-mediated WoZ, however, the wizard must represent the identity, interpersonal style, and relational norms of a specific individual through the proxy system. This requires enacting how the individual would communicate, adapt, and set boundaries in a given social context, rather than reproducing scripted behavior. Since individuals vary their communicative behavior across situations, audiences, and relationships, representing a person through a proxy cannot rely on a single fixed notion

Table 1: Methodological Shifts for Proxy-Mediated Wizard-of-Oz

Reconceptualizing the Wizard Role (§3.1)
Identity representation: Wizard determines which aspects of the source's communicative patterns are most salient in a given interaction.
Interpretive judgment: Wizard applies learned patterns of the source's communicative patterns to new or ambiguous situations.
Contextual grounding: Wizard relies on structured training and contextual information to guide appropriate proxy behavior.
Reconsidering Performance Metrics (§3.2)
Source perspective: Whether the proxy accurately represents the source's intent and relational norms.
Partner perspective: Whether interaction partners perceive the proxy as consistent with relationship expectations.
Shared perspective: Whether the proxy's participation is reliable and acceptable throughout the interactions.
Recognizing Social and Ethical Implications (§3.3)
Authorization: Whether the proxy has appropriate authority to act on behalf of the source within defined conditions and limits.
Disclosure: Whether delegation is clearly communicated so partners can calibrate trust and expectations.
Accountability: Whether responsibility for proxy actions can be traced across the source, wizard, and system.

of system behavior. Therefore, the proxy-mediated WoZ reframes identity capture as a design problem that determines which aspects of a person's communicative repertoire are salient for a particular interaction and how to prioritize them when they diverge.

As identity cannot be fully specified in advance, proxy-mediated WoZ operation requires interpretive judgment. Wizards must learn the source's typical linguistic patterns, decision-making tendencies, and relational norms, while applying this understanding to novel situations in ways that the source would consider appropriate. This requires structured training with clear learning materials and representation boundaries, as well as access to relevant contextual information, including communication history, delegation constraints, and relationship-specific norms. HCI research has established role-playing and performance-based design methods to identify situated behaviors before system specification, using enactment to surface interaction dynamics [2, 5, 12, 24]. Drawing on these methods, proxy-oriented wizards can develop interpretive judgment through structured enactment of the source's communication patterns, iterative calibration with the source, and improvisation exercises that probe boundary cases.

- **Identity scope and salience:** Which aspects of the source's communicative repertoire are treated as relevant in a given interaction (e.g., tone, formality, directness, boundary-setting), and how are conflicting traits prioritized when they conflict?
- **Interpretive judgment and adaptation:** How does the wizard apply learned patterns of the source's behavior to novel or ambiguous situations, including managing uncertainty, competing norms, or incomplete information?
- **Contextual grounding and boundary management:** To what extent does wizard have access to relevant contextual information (e.g., communication history, relationship-specific norms, delegation constraints) when representing the source, and how are limits or ambiguities in representation communicated when necessary?

3.2 Redefining Performance Metrics

Since proxy-mediated WoZ treats wizarding as identity representation, evaluating proxy behavior cannot solely rely on fluency or task performance. Traditional WoZ metrics, such as response timing, task success, and perceived naturalness, remain useful to identify functional features, but they are insufficient as primary indicators of proxy performance. Evaluating proxy performance only through functional criteria risks overlooking socially meaningful failures. For example, a proxy may violate a relationship norm, overstep a delegation boundary, or communicate in a way that feels inconsistent with the source user, even if the response itself is competent. In such cases, the interaction may appear successful by traditional measures while undermining trust or legitimacy in practice.

We therefore frame proxy performance in terms of social legitimacy, evaluating whether the proxy participates in interaction in ways that are acceptable to those involved in the exchange. This requires examining proxy behavior from the perspectives embedded in proxy-mediated interaction: the *source*, who evaluates whether the proxy accurately represents their communicative identity and intentions; the *interaction partner*, who assesses whether the proxy's behavior is appropriate within the relationship and interactional context; and their shared perspective, which reflects whether the interaction remains acceptable and sustainable over time. These perspectives highlight different aspects of proxy legitimacy, which we examine through three evaluation dimensions:

- **Recognition of representation (source perspective):** Does the source user consider the proxy's actions consistent with their intent, identity, and relational norms?
- **Alignment with relationship norms (partner perspective):** Do interaction partners interpret the proxy's behavior as consistent with established relationship expectations rather than as impersonal or system-generated?
- **Contextual acceptability over time (shared perspective):** Do both parties consider the proxy's participation acceptable across the course of interaction, including before, during, and after proxy-mediated exchanges, and where do their assessments diverge?

3.3 Recognizing Social and Ethical Implications

Proxy-mediated interaction carries social and ethical risks, as delegated actions are interpreted through social relationships rather than evaluated solely in terms of output quality. Even when a proxy produces plausible responses, acceptance depends on whether others treat the proxy's actions as a legitimate extension of the source. In practice, this raises recurring concerns around authorization (i.e., what is being delegated, to whom, and under what stakes) and disclosure (i.e., how delegation is signaled so that interaction partners can calibrate trust and expectations).

These concerns are equally present in proxy-mediated WoZ, where accountability is distributed across multiple actors. When a proxy is treated as an extension of the source, its actions—even when partial, distorted, or contextually inappropriate—may be attributed to the source rather than to the system. When misrepresentation occurs, responsibility may become ambiguously distributed across the source, the wizard-as-performer, and the proxy system interface, creating situations where blame falls on the wrong actor or accountability becomes difficult to trace.

For these reasons, ethical issues in proxy-mediated WoZ should be treated less as abstract principles and more as protocol-level design variables. Studies can explicitly manipulate and document what authority is granted, what disclosure is provided—to whom and when—and how correction and responsibility are handled. This enables researchers to observe when legitimacy holds, where it breaks down, and which safeguards may be necessary before deploying autonomous proxy behavior at scale. We operationalize ethical and social considerations in proxy-mediated WoZ through three dimensions:

- **Authorization and scope of delegation:** What actions are delegated, under what conditions, and with what limits (e.g., task boundaries, relationship-specific constraints, stakes of the interaction)?
- **Disclosure and expectation calibration:** How is delegation signaled to interaction partners, and when, so they can appropriately interpret the proxy's role?
- **Accountability and correction:** How is responsibility assigned when proxy behavior causes harm, including how errors are corrected, and how accountability is made visible across the source, wizard, and system?

4 CONCLUSION

We contribute a structured analysis of how proxy-mediated interaction reconfigures key dimensions of WoZ methodology. Specifically, we articulate how the wizard's role changes from system operator to identity performer, how evaluation must move beyond functional success toward social legitimacy, and how ethical concerns such as authorization, disclosure, and accountability become protocol-level design variables rather than abstract principles. By reframing WoZ as a method for designing and studying proxy-mediated interaction, this work provides methodological guidance for treating proxyhood as a relational and socially established phenomenon, and suggests directions for future research on representation, legitimacy, and accountability in human-AI interaction.
