Abstract

AI writing support is becoming increasingly popular, offering vast potential for design innovations that cater to diverse user needs. This project focuses on empowering individuals with different personalities by co-designing personalized AI writing companions. Through participatory design workshops, we explored the integration of personality-based preferences into AI writing assistants, using the MBTI dimensions related to information processing as our framework. Specifically, we articulated the functions that a writing companion should have to assist users, the personality traits that should be embodied by the companion to foster engagement, and the visual design elements that contribute to user satisfaction. We identified both consensus and distinct personality-based preferences across these dimensions, providing actionable design strategies for creating personalized, user-centered AI writing tools. This work advances the understanding of how personality influences writing support preferences and contributes to the broader field of human-AI teaming research.

1 INTRODUCTION

Personality plays a key role in shaping writing styles and preferences, sparking interest in developing strategies to support diverse writing approaches. Existing research has explored the relationship between personality and writing. [9] examined how different personality types influence individual writing processes, suggesting that understanding a writer's personality can inform tailored writing instruction, potentially improving writing efficacy and comfort. The Myers-Briggs Type Indicator (MBTI), based on Carl Jung's theory of psychological types [10], is a widely used personality assessment tool developed by Myers and Briggs [15]. It classifies individuals into 16 types across four dichotomies: Extraversion/Introversion (E/I), Sensing/Intuition (N/S), Thinking/Feeling (T/F), and Judging/Perceiving (J/P). MBTI has been extensively applied in research areas such as leadership [19], team dynamics [4], and communication [8]. Despite critiques regarding reliability [16], MBTI remains a valuable tool for examining the relationship between personality and behavior across applied contexts, with unique advantages such as accessibility and popularity among the general public. Based on MBTI, [7] generated four writer profiles: Correspondents (SFs) for empathetic, audience-centered writing; Technical Writers (STs) for logical, precise content; Creative Writers (NFs) for innovative, motivational pieces; and Analytical Writers (NTs) for conceptual, problem-solving writing. The study offers tailored training strategies to leverage each type's strengths, thereby improving writing effectiveness and organizational communication.

With the recent proliferation of AI writing tools, there are growing opportunities to consider personality in AI-supported writing. Existing research on writing agents largely focuses on tools for specific writing tasks, such as English learning [6], scientific review [11], peer-review [22], and fiction/story writing [24]. While some studies explore broader design spaces for AI writing assistants [20, 25, 26], they often lack thorough engagement with users during the design process. This limits their ability to holistically

address user experience and identify specific needs in the human-AI co-creation process, particularly in accommodating individual differences. Among the initial efforts in this direction, [23] introduces a theoretical framework that integrates AI with MBTI to improve team performance in organizational settings. The framework highlights how AI capabilities can complement MBTI personality types, particularly focusing on S/N and T/F dimensions. By categorizing teams into four types—Visionary (NF), Strategic (NT), Supportive (SF), and Operational (ST)—the study proposes that AI can augment team dynamics by aligning with these specific compositions. In this study, we focus on individual experiences with AI as writing companions, considering their personality type. Aligning writing companions with writing tasks, composition processes, and communication styles varied by personalities informs the diverse writing agent design over a one-size-fits-all model.

Using MBTI as the primary framework, we conducted eight participatory design workshops, recruiting participants on N/S and T/F dimensions. These dimensions were chosen because they are particularly relevant to writing styles and habits and are supported by previous studies [7, 23]. Intuition (N) vs. Sensing (S) describes how individuals take in information: Ss focus on concrete details and present realities while Ns on abstract ideas and future possibilities. Thinking (T) vs. Feeling (F) explains how people make decisions: Ts rely on logic and objective criteria, and Fs are guided by empathy, personal values, and the impact on others [15]. To maintain clarity in our exploration and avoid overly complex groupings, we prioritized those most directly relevant dimensions and excluded E/I and J/P due to their primary relations to social energy and organization styles rather than writing behavior and cognitive patterns.

Our research seeks to explore different processes and preferences in collaborative writing with AI across personality types, prioritizing external user needs over solely algorithmic solutions. Specifically, we ask: **What are the design priorities of the writing companions among people with different personalities?** To address this, three design-specific questions were derived:

- DQ1: What functions could a writing companion have to assist users in writing?
- DQ2: What personality could a writing companion have to facilitate engagement?
- DQ3: What would the visual embodiment of a writing companion look like?

Grounded in the human-AI teaming discourse [5, 27, 28] and team science principles [18, 21], we aim to provide actionable design guidelines for developing diverse, socially-conscious, and inclusive AI writing tools that foster engagement and enhance collaboration productivity across varied cognitive styles.

2 METHODS

We adopted a participatory approach to address the needs of users with diverse personalities and uncover design space for AI writing companions. Participatory design (PD) actively engages end-users in the design process to capture their concerns, requirements, and ideas [12, 13]. Through eight workshops with 24 participants grouped by personality traits, we explored desired features, personalities, and visual embodiment for a writing companion. This

exploratory study serves as an initial step, shedding light on the development of personality-specific prototypes for writing tools.

We recruited participants from a U.S. public university via email lists and an online research participation pool. To capture diverse MBTI personality types, a screening survey was conducted to collect demographic data, personality type, writing self-efficacy [3], and design experience. We focused on two MBTI dimensions (N/S and T/F), creating four personality groups: NF, NT, SF, and ST. Among willing participants, we also considered the E/I and J/P dimensions, gender, writing self-efficacy, and design experience to ensure balanced representations. The final sample included 24 participants, six per personality group. They were grouped into workshops of three to facilitate better control and interaction depth. The average age was 23.9 ($SD = 3.84$), with 10 males, 13 females, and one genderqueer. The average writing self-efficacy score was 72.9/100 ($SD = 17.67$). Eight participants had design experience, four had some, and nine had none (participant details in Appendix A).

The 75-minute in-person participatory workshops included activities to encourage both individual reflection and collaborative discussion, consisting of: 1) an introduction to the research objectives, participatory approach, and workshop processes; 2) a discussion on participants' writing styles and experiences, such as what is considered good writing and their challenges in writing; 3) drawing flowcharts to illustrate their typical writing process, with highlighted steps involving Generative AI (GAI) and its role of assistance, followed by group sharing and discussion; 4) a brainstorming session on desired companion functionalities, where participants individually documented or sketched ideas on sticky notes, proposing both improvements to existing tools and new possibilities. These ideas were then presented for collaborative discussions to identify common themes and develop new concepts; 5) creating a persona sheet for their ideal companion to specify preferences for its role, personality traits, communication style (tone, emotional range, response detail), and its handling of inaccuracies or misaligned suggestions (see Figure 1A); and 6) describing their preferred appearances for the companion (e.g., human, animal, or object) and composing a mood board [14] to visually express their envisioned interaction vibes, translating abstract ideas into tangible visual expressions (see Figure 1B).

All workshops were recorded with participant consent. Thematic analysis [2] was conducted by two researchers who independently coded the transcriptions before reconciling differences and refining the codebook through an iterative process. The final code structure aligned with the workshop, categorizing major themes as writing styles and preferences, desired functions, personalities, and visual embodiments. Example sub-themes included “*Definitions of Good Writing*,” while smaller topics centering around personality-specific insights, such as “*S Trait: Provide Reasonings in Output*.” All insights contributed to a nuanced design space for AI writing companions.

3 FINDINGS

3.1 Writing Preferences and Process

3.1.1 General Writing & Preferences in Writing. In response to our question about **what constitutes good writing**, all participants across personalities agreed on clarity, logical structure, and smooth transitions as key characteristics. Beyond this consensus, distinct

Figure 1: Example Workshop Activities: (A) Desired Function Brainstorming and Persona Construction, (B) Mood Board Creation.

perceptions aligned with prior variations on writing styles [7]. N participants emphasized narrative quality, with NTs prioritizing precision and reliability (P7, P8). T participants valued clear and factual technical writing (P12, P19, P20, P22). F participants focused on evoking emotions and fostering personal connections, with SFs blending logic and emotional appeal for balanced, audience-centered writing, and NFs valuing empathy to create expressive content (P2, P3, P5, P18). **Writing strengths and challenges** were also influenced by personalities. N participants often struggled to transform abstract ideas into clear and cohesive text. While NTs excelled in structured tasks like research papers, they found creative writing challenging (P7, P8). F participants were skilled at creating emotional connections but sometimes lacked clarity in expressing these emotions. NFs especially faced difficulty organizing ideas effectively—resulting in disjointed writing, while SFs struggled with logic-driven writing, especially in academic tasks like research papers. T participants excelled in structured tasks like methods but found it challenging to condense complex ideas into concise formats or ideate and tailor content to specific audiences (P19, P20). Participants’ preferences for **writing instructions** also varied by personalities and their needs for structure and creativity. T participants generally favored specific, concise, and structured guidance, with NTs prioritizing clarity and focus through detailed instructions, and STs preferring precise, goal-oriented directives. In contrast, F participants valued instructions that encouraged creativity and personal expression, avoiding restrictive or detailed formats. Among Fs, NFs liked open-ended prompts that facilitated idea exploration (P5) while SFs sought a balance between structure and flexibility, emphasizing the need for clarity and adaptability (P13, P14, P17).

3.1.2 Writing Process with AI Usage. Most participants emphasized a **structured writing process and iterative refinement**, though approaches varied by personality. N participants prioritized abstract thinking and idea generation. NTs focused on logical consistency, using detailed outlines to avoid “*wandering off topic*” (P8), while NFs leaned into creative ideation, often through “*idea vomiting*” or integrating emotional resonance into writing (P6). T participants valued precision and focused on structured, time-effective workflows: while NTs regularly used external resources to streamline ideation (e.g., GAI) (P10), STs focused on producing pragmatic

drafts to achieve clear goals (P19, P22). For F participants, dynamic ideation and transitioning from divergent to convergent thinking were key aspects. SFs began with broad idea generation and refined their work with supportive materials to select the best options (P16), whereas NFs integrated emotional resonance, reworking their thoughts into cohesive narratives (P18).

All participants **relied on AI tools to enhance their writing**, commonly for brainstorming, language refinement, and grammar checking. Tools like Grammarly¹ and ChatGPT² were often used for grammar checks, sentence rewording, and improving idea flow. Despite shared practices, each personality group applied AI in unique ways tailored to their writing needs. NT participants demonstrated a strategic approach to AI usage, focusing on leveraging AI for ideation and resource validation. For instance, P8 and P10 relied on ChatGPT to explore research directions, validate ongoing ideas, also refine and critique their work. NF participants approached AI collaboratively and creatively, such as assessing abstract ideas. For instance, P4 and P18 asked ChatGPT questions like, “*Do you think this is interesting?*” or “*Has this been done before?*” Other NFs applied AI at a later stage, using AI to translate quick, messy drafts into polished sentences, or to extend paragraphs and articulate thoughts more clearly. ST participants adopted a practical, results-driven approach. P19 and P24 used AI to brainstorm subtopics and generate supporting evidence, P22 applied ChatGPT to consolidate scattered thoughts into coherent outlines, refining transitions and overall structure. SF participants exhibited pragmatic yet emotionally attuned AI usage, primarily for brainstorming and fluency. Most SFs relied on AI to search for relevant materials after main ideas were formed. Others like P15 used ChatGPT for self-assessment, comparing their work against rubrics to identify areas for improvement and ensure clarity.

3.2 Desired Functionalities for AI Writing Companions (DQ1)

This section outlines functional design spaces shaping an AI writing companion, organized by writing, interface, communication, and algorithm components. Appendix B illustrates a word cloud of

¹<https://app.grammarly.com/>

²<https://chatgpt.com/>

Figure 2: Example Design Sketches during the Workshop: (A) Providing Reasoning Side-by-Side, (B) Chat Organization, (C) Emotional Scale and Rush/Casual Mode.

key features across personalities, with prominence reflecting more frequent mentions by participants.

3.2.1 Writing/Response Style. Participants sought features that tailored content generation to their individual styles, with many (7 of 24) emphasizing the need for the companion to **adapt to their writing style and tone** by remembering and referring to prior inputs and interests. Suggestions included a slider to adjust the retention of the user’s writing style (P9) and the option to receive two versions of outputs: one standard AI-generated and one reflecting the user’s style (P15).

Built upon the personal style, a recurring theme among five N participants was a **persona feature**. While existing tools (e.g., ChatGPT) allow users to input background and preferences, they appear to be insufficient. Suggestions included having the companion learn users from an account-opening survey besides users’ input. P7 notably proposed a **switchable persona feature**, allowing users to select from multiple pre-set profiles based on their current needs (e.g., “student” for clarity and precision, “project manager” for business-oriented communication and structured crafting, “club organizer” for creative ideas and engaging language). P3 additionally suggested that the companion could also embed personas to suit different groups (e.g., simpler language or slang for Gen Z).

Response customization was another priority, especially for S and T participants. Four requested more options to adjust tone (formal to casual), focus (e.g., clarity, grammar), and context (e.g., academic, creative). When asking for revisions, the detailed-oriented S participants wanted better **revision tracking**. P22 and P23 praised Grammarly’s interface for easily spotting changes, with P23 proposing a toggle to bold/unbold changes. P15 and P23 also sought before-and-after comparisons side-by-side or click to switch between versions. S participants also emphasized the need for the companion to explain its suggestions, showing their attention to detail and concreteness. Four requested **rationales for revisions**, with suggested layouts including a side-by-side panel (see Figure 2A), an explanation list at the end, hovering over changes to view reasons, and a toggle to show/hide reasons. However, participants across all personalities valued **flexibility in revising suggestions**, with seven recommending the option to request multiple wording substitutes (e.g., click to request and review).

Some minor features were also discussed. Participants mentioned **citation-related** functions, but STs (P20, P24) desired auto-generated citation lists and the options to see/unsee citations, while NFs (P4, P5) cared about credibility indicators (e.g., a “verified label” for trustworthy sources). STs (P21, P22) also expressed interest in receiving **evaluations of their writing**, such as numerical grades, reading levels, and reading time.

3.2.2 Interface Usability. This theme centers on interface and visual elements for the usability needs of diverse users. Six intuitive and feeling-oriented participants (N, F, or both) highlighted the need for **customizable interface**, particularly adjusting colors and backgrounds to align with their cognitive styles and emotions. Three NFs (P4, P5, P6) further depicted task-based scenarios (e.g., plain for coding, vibrant for creative writing, beach for travel itineraries) or time-based variations (e.g., “sky blue” for mornings, “orange” for lunchtime). Besides visuals, P1 (NF) also articulated a multitasking layout to improve usability, with blocks for the main task, thought tree, checklist, sources, AI conversation, and history panel to support task integration and mental organization. Beyond the interface, NF also discussed the possible **interaction paradigm** to enhance social and emotional attachment. P2 envisioned a spatial computing environment (e.g., AR) where the companion could “*be a 3D buddy, standing there, understand my vision, and say ‘Hey, you make a mistake here!’*” to offer real-time and collaborative interaction.

Another common preference, especially among Ns, was **chat organization** (see Figure 2B). P4 and P11 wanted the ability to combine similar chats or organize them into custom collections for better management and faster retrieval (e.g., by projects, topics, or usage focus). In addition to chat, P7 proposed a **“prompt catalog”** to save or favorite frequently used prompts into a library, streamlining repetitive typing tasks and fastening access. NFs also offered ideas reflecting their flexibility and collaboration traits, including sharing chats for joint editing (P6) and a Photoshop-like history panel to jump between steps for outcome experimentations (P1). Only one ST participant (P19) mentioned the chat interface function but still insightful. He proposed an **auto-generated table of contents**, with modifiable anchor points (similar to Google Docs), to improve within-chat navigation and topic organization for those who prioritize precision and efficiency.

3.2.3 Communication Style. Communication style highlights how the writing companion interacts with users around tone, conversational structure, and engagement. Participants, particularly Ns and Fs, dominated insights on **emotional appeal**. Three Ns suggested that the companion's tone could be imbued with greater emotion and expressed the enhanced support given by anthropomorphism. Yet, F participants also acknowledged drawbacks of overly friendly communication. P5 explained, *"I don't think the seemingly friendly tone really helps users improve their writing skills. Instead, it just violently changes it to a certain style."* In response, three Fs (P5, P6, P13) proposed a **"dragging emotional scale"** to adjust the companion's critique level based on user goals or preferences (friendly to harsh) (see Figure 2C). P6 further mentioned the option to disable emotional elements for users in a rush.

NFs also shared unique preferences for dialogue style. For example, P5 sought **more guiding questions** that fostered cognitive engagement rather than plain answers. He felt that always receiving answers *"won't become a knowledge of mine."* Following this, P5 and P6 envisioned a **"rush/casual mode"** to adjust the dialogue style (see Figure 2C). In "casual mode", the companion would act like a teaching assistant, prompting thoughtful discussions and facilitating reflection, while the "rush mode" would prioritize efficiency to provide direct answers without unnecessary conversations.

Participants across personality types criticized mono-initiated conversations by users and widely supported the companion to **auto-initiate interactions**, though preferences varied. NF participants favored life and social connections, such as greeting with engaging messages upon opening the app (P4), proactively talking about context-aware suggestions (P2), and popping up timely reminders or alerts (P3). In contrast, ST (P20) and NT (P9) focused on practical, task-focused initiation. They valued a Word or Google Docs plug-in that could deliver contextually relevant ideas or feedback along with their ongoing thinking flows. P9 further recommended customizable thresholds for such auto-messages by frequency (e.g., every 20 mins) or severity (e.g., *"disturb me only for harsh problems"*), ensuring the support fits the work context and minimizes unnecessary interruptions.

3.2.4 Algorithm and System Capabilities. This theme focuses on the backend technical features that enhance functionality, with ideas scattered across personalities. Participants expressed a desire for **better memorization** of user history for more personalized and accurate responses. **Enhanced language quality** was also requested for smoother phrasing, better paragraph connections, and avoiding distinct AI jargon. Subtle uniqueness was identified for Ns and Fs. They favor **visual/asset creation** to support ideation and writing, such as thought trees, idea webs, and diagrams. N participants also went for **integrating with external tools**, such as enabling the companion to plug into external applications and the ability to indicate the cited parts from documents.

3.3 Desired Personalities for AI Writing Companions (DQ2)

Participants had diverse expectations for the **writing companion's role**, reflecting their personality preferences. NF participants envisioned the companion as a motivator or supporter, emphasizing emotional connection and encouragement to enhance interaction

and the writing process. They often viewed it as a "friend," with P2 even delineating *"a toy with a Mickey Mouse voice."* Generally, NFs gravitated toward a warm, supportive, and creative companion with friendly, energetic, or empathetic tones. In sharp contrast, STs were inclined to a more task-oriented and practical approach, viewing the companion as a "tool." They sought to maintain the dominant role, with their companion acting as a passive assistant, follower, or info receiver. P21 specifically described the ideal companion as *"an engine."* Emotional elements were not STs' target but professionalism, intelligence, and straightforwardness, focusing on the companion's efficiency and functionality. Interestingly, SFs and NTs, being more moderate personalities, had more balanced and neutral expectations. Besides answers similar to those above, they also described ideal companions as friendly, patient, and reliable partners or collaborators, combining warmth with function.

Key distinctions in **conversation style** emerged between N and S participants. Ns, particularly NFs, uniquely appreciated guiding questions that prompt deeper thinking, aligning with their preference for creative and reflective processes. Ss, oppositely, preferred pragmatic, results-oriented interactions with direct answers and specific reasoning. Differences between Fs and Ts were also evident in responses to **companion's errors**. F participants preferred an apologetic tone, while T participants explicitly stressed, *"don't apologize to me"* (P9, P24) but *"explain what part is wrong"* (P8, P22, P23). Despite differences, both Fs and Ts desired alternative suggestions to resolve the issue.

3.4 Desired Visual Embodiments for AI Writing Companions (DQ3)

When considering the **visual embodiment** of the writing companion, Fs and Ts showed clear preferences. Eight F participants were drawn to designs that conveyed friendliness and approachability, such as cute animals or anthropomorphic representations. However, three T participants opted for robots because *"it is close to the machine nature"* (P8), or abstract shapes symbolizing intelligence and professionalism. Four Ts even explicitly preferred the existing text-based version, reinforcing their focus on efficiency and simplicity. Across personality types, there was a shared aversion to human-like avatars, with comments like *"very scary to me"* (P8) or *"horrible"* (P15). **Color preferences and overall vibes** mirrored the emotional and practical divide. F participants favored emotional dynamics such as pastel, vivid, or peaceful tones. T participants, however, prioritized *"simplistic, not too distracting"* (P19, P23). They desired muted, calm palettes or purely black-and-white, showing their minimalist and practical tendencies.

4 DISCUSSION AND FUTURE PLAN

4.1 Summary of Findings

We conducted a participatory design study to explore the design space for personality-specific AI writing companions. Our findings reveal diverse challenges, preferences, and AI usage patterns in writing. We also identified key technological features desired across personality types. We found that all personalities valued features like generating outputs in their writing style, offering multiple revision substitutes, and auto-initiating contextually relevant feedback.

However, differences also emerged: S and T participants prioritized efficiency-oriented supports like detailed response settings, revision tracking, and reasoning-based suggestions, while N and F participants desired tools to foster creativity and emotional connection, such as interface customization, task-specific personas, and adjustable communication styles. Personality also shaped communication preferences: NF participants envisioned a warm, supportive, or energetic companion as a “friend”, valuing guiding questions over machine-like Q&A. Conversely, ST participants preferred professional or straightforward conversations, treating the companion as an intelligent and efficient “tool”. Interestingly, this divergence was mitigated in SFs and NTs—the moderating personalities blending bipolar traits (NF and ST)—into a more neutral and balanced desire for patient, reliable “collaborators”. Visual preferences also reflected distinctions: F participants favored friendly, vivid representations with dynamic colors that resonated emotionally, while T participants preferred simple, technical designs, even the existing text-based version, with muted, minimalistic vibes to reduce distraction. These insights enrich human-AI teaming considerations, such as AI teammates’ characteristics, engagement levels [27], team relationships [5], and adaptability [28].

4.2 Opportunities for Future Plan

Limitations exist in our study that suggest future directions, one of which is the choice of MBTI as the personality framework over Big Five [17]. While we advocated that MBTI focuses more on cognitive functions like information gathering and processing, offers simpler dichotomies that can be easily applied in practice, and enjoys familiarity with the public, it may not capture the full complexity of personality. Future research could investigate correlations and differences between MBTI and Big Five, or employ Big Five to uncover more insights into the dynamics between personality and human-AI co-writing. We also only incorporated two MBTI dimensions, future research could incorporate insights from E/I and J/P to enrich our understanding. By pre-grouping participants based on MBTI, biases might also occur as some talkative individuals potentially steer the discussions and mask subtle personality differences. Moreover, participants’ self-reported traits may have been influenced by MBTI stereotypes and may not accurately reflect how they behave in real-world settings.

Despite limitations, our study identified shared preferences while uncovering meaningful personality-driven differences in AI writing assistants. Consistent with existing literature [23], we observed diverging preferences in human-AI collaboration and reinforced the importance of “team match” [1], where aligning AI dynamics with individual needs enhances performance and satisfaction. By contributing user-centric insights, this study articulates the design space for AI writing companions, paving the way for the development of adaptive systems that support diverse users and their writing processes. However, the current study did not empirically test whether personality-based AI customization improves writing outcomes, which limits the ability to assess its practical impact. Our next step is to integrate these insights into personality-based prototypes and conduct user testing to evaluate their impact on writing performance and user satisfaction, while also collecting feedback for further refinement. Ultimately, we hope to advance

inclusive, responsive AI systems that promote effective human-AI collaboration and optimal team building.

5 Conclusion

Using MBTI framework, this study explores the intersection of personality and AI-assisted writing. We investigated the desired functions, personalities, and visual embodiments for AI writing companions across different personality types, identifying key insights into how AI writing companions can be tailored to better support diverse cognitive styles and enhance human-AI team collaboration. Our findings emphasize the importance of aligning AI tools with individual needs and moving beyond one-size-fits-all solutions. Through user-centered design, we aim to foster more inclusive, adaptable AI systems that enhance user experience and writing productivity.
