Abstract

This paper explores the GenAI networked privacy problem in the professional use context. Utilizing a survey of GenAI users, our study demonstrates the importance of disclosure comfort, shaped by privacy perceptions related to control and fairness, and knowledge of GenAI privacy controls in driving professional information disclosure. Our findings provide initial evidence of the GenAI networked privacy problem and the need for both (i) further research to deepen our understanding and (ii) efforts from organizations to educate and empower their employees to engage in behaviors which lead to better networked privacy management in this context.

1 Introduction

While artificial intelligence technologies have been expanding in capability for many years, generative artificial intelligence (GenAI) represents a large shift in awareness and adoption among the general population. GenAI technologies are the latest wave of computational advancements that leverage human-like intelligence capabilities to solve complex problems, generate new content (text, images, code, and video), and otherwise interact with people [35]. As the breadth and depth of GenAI applications expand, what remains largely out-of-focus are the potential privacy risks. GenAI presents large-scale risks to networked privacy [13, 22]. Forwarded by Boyd (2012) [3], networked privacy refers to instances when a person's privacy is affected by other people related to the data. In this context, networked privacy violations can occur when user inputs are leveraged by GenAI applications to train their models, storing and retrieving long-term information within a vector database. In this way, user inputs are comingled with public data, and can be recalled to varying degrees by other users [36]. Not only can attacks be used to extract ChatGPT training data [5], but unsuspecting users may find portions of their online content crop up during non-malicious interactions as their input trains the model to produce similar material for other people. Figure 1 depicts the GenAI networked privacy problem.

Users may be especially incentivized to share sensitive professional information with GenAI applications. Competitive environments and stressful time pressures can lead to 'organizationally deviant' behavior in violation of organizational rules and norms [15, 29], such as inappropriate online disclosures. For instance, a software engineer out of their depths on a project may ask a GenAI application for advice; An academic strapped with paper review responsibilities may upload a paper for GenAI to review; An overworked instructor may have a lapse of judgment and use GenAI to create a student seating chart, risking a FERPA violation (Family Educational Rights and Privacy Act [32]). As these examples illustrate, many professional circumstances lead to sharing of sensitive information, meaning that individuals and organizations have a vested interest in GenAI networked privacy.

Figure 1: GenAI’s networked privacy problem. Users provide personal, interpersonal, and organizational information to GenAI tools for response or editing (Panel 1). Users who do not opt out will have their data used for GenAI algorithm training, committing the data to long-term memory (Panel 2). Non-malicious inquiries and malicious attacks within the GenAI platform’s network can recall the data to varying degrees (Panel 3). A portion of this data will be sensitive and impact the privacy of others (Panel 4)

Calls for research reflect accumulating evidence of the GenAI networked privacy problem. This includes both vulnerabilities in the GenAI technologies themselves and privacy incidents stemming from users’ disclosure behaviors. In terms of the former, a 2023 vulnerability in ChatGPT resulted in the presentation of private data including names and financial details to other users [27]. In terms of the latter, several organizations have been involved in public incidents. For example, Samsung has been involved in three separate leaks of proprietary information from ChatGPT, including a company meeting transcript and proprietary information [24, 25, 40]. In the research context, experimental studies are fast emerging, demonstrating that when LLMs are fed a users’ online posts, they are highly successful at drawing inferences about individual users including private information which the user did not intend to reveal [33]. Additional studies demonstrate the low cost and ease at which LLMs will reveal sensitive, personal information including social security numbers [4]. In a broader sense, the accessibility that Co-pilot has to all users’ data and files has raised concerns regarding privacy and potential leaks [24]. These risks all stem back to excessive disclosure behaviors among GenAI users, particularly in the professional context. Indeed, both industry reports e.g. [1] and qualitative research studies [16, 41] find that GenAI users disclose various data types including employees and customer data. Notably, individuals and organizations may not realize when their sensitive information has leaked due to the nature of GenAI information sharing, allowing more time for the information to spread. Taken together, the scientific community is only beginning to understand the nature of GenAI privacy risks.

With early adopters in the hundreds of millions and preliminary work highlighting downstream privacy impacts, the human element of GenAI networked privacy must be considered early. This research represents a first step toward addressing the overarching research question of *how GenAI privacy perceptions relate to professional disclosure?* We utilized a mixed-method approach to examine survey responses from a large sample of demographically-diverse GenAI users reporting to use the tool for work purposes, examining the relationship between GenAI professional disclosures and privacy knowledge, and perceptions. Our research complements prior work

by systematizing understandings of GenAI professional disclosure decisions and answers calls for research focusing on individuals’ disclosure behaviors and related risk perceptions [41]. We apply insights from foundational privacy disclosure literature to emerging technologies, identifying key facets that drive GenAI professional disclosure. This work contributes to the long-term goal of designing user-centered interventions that educate and empower users to protect private information of themselves and others.

2 Hypothesis Development and Proposed Research Model

In order to investigate how GenAI users’ privacy perceptions and knowledge shape disclosure, we develop the model shown in Figure 2. We focus on disclosure comfort, or the level of comfort individuals feel when disclosing different data types to GenAI applications for two reasons. First, while privacy concern is a popular proxy for measuring privacy [7], it is widely acknowledged that privacy cannot be effectively measured. Privacy is a complex belief, which can be influenced by general privacy perceptions, contextual factors, and situational factors [6]. The exploratory nature of this work does not allow for a comprehensive measurement of privacy, while also providing the opportunity for a different approach to exploring privacy in this new GenAI context. Second, users’ comfort and/or discomfort emerged in qualitative works as a key driver of disclosure behaviors in the GenAI context [16, 41]. The first set of hypotheses focus on the relationships between privacy perceptions at the situational level and individuals’ comfort in disclosing data. Perceived control refers to individuals’ belief that they can control the privacy of their data when interacting with a specific technology [11, 21], in this case GenAI technologies. Perceived control has been found to reduce privacy concerns in websites requiring different types of data disclosure [38], location-based services [39], and to increase perceptions of privacy in the broad online context [7] and situational contexts namely contact tracing applications [11]. While perceived control has not been explored in the GenAI context, we argue if GenAI users believe they control information they disclose when utilizing GenAI tools, they are more likely to express

higher levels of comfort disclosing data. Thus, we propose: *H1a. Perceived control is positively associated with disclosure comfort.*

The second perception we examine is perceived fairness or individuals' views towards the appropriateness of how GenAI tools utilize private data to train their models. Fairness perceptions in the privacy literature focus on individuals' perceptions of whether an organization's privacy-related activities such as how they utilize private data are appropriate and fair [19]. Fairness relates to the power-equilibrium model (PRE) of privacy developed by Lwin et al. (2007) [20], which holds that consumers who perceive that organizations are acting responsibly in their privacy practices show less privacy concern. PRE has been extended to include personal beliefs of fairness [19]. In the GenAI context, it is widely known that data disclosed is leveraged to train the models. Indeed, in a recent qualitative study, the link between fairness and disclosure was raised with one participant describing this as a 'fair exchange' for use [41]. We argue that if respondents view the use of data to train models as fair, they will express higher comfort in disclosing. Thus, we propose: *H1b. Perceived fairness is positively associated with disclosure comfort.*

The second set of hypotheses focus on privacy knowledge factors. It has been argued that GenAI users may lack awareness of the risks their disclosure behaviors may create [16]. Thus, we argue that those with greater awareness or knowledge of privacy in this context, may express different levels of disclosure comfort. The first variable is privacy media coverage awareness, or the frequency of news stories related to GenAI privacy incidents respondents have been exposed to. Privacy media coverage has been found to increase privacy concerns in the organizational context [30], and health privacy context [10]. GenAI technologies have attracted huge volumes of mainstream news coverage detailing privacy incidents and risks associated with these technologies. Thus, we argue that if individuals are aware of these media stories, they will express lower levels of comfort disclosing data.

H2a. Privacy media coverage awareness is negatively associated with disclosure comfort.

Second, we leverage privacy controls awareness, or individuals' confidence in their ability to leverage the available privacy controls GenAI tools offer including turning off prompt memorization and chat storage functions. These privacy controls are offered by the leading GenAI tools such as ChatGPT, but users may not be aware of this. Indeed, in a recent study of GenAI users, only 3 of 17 participants expressed awareness of these privacy controls, with these respondents discussing the difficulties faced in locating and leveraging these controls [16]. In another study, all participants were unaware of privacy control features but believed these features were useful upon being informed by the researchers [41]. Calls have been issued to quantitatively investigate privacy controls awareness [41]. We propose that individuals who are not just aware of these features but are confident in their ability to exercise these controls, are likely to express higher disclosure comfort.

H2b. Awareness of privacy controls is positively associated with disclosure comfort.

Lastly, we explore the link between disclosure comfort and actual disclosure behaviors. We argue that individuals' broad disclosure comfort shaped by their situational GenAI privacy perceptions and knowledge, will drive their disclosure behaviors. Put specifically,

we propose that a higher comfort level in disclosing data related to oneself and others will result with higher disclosure of data in the professional context.

H3. Disclosure comfort is positively associated with disclosure behavior.

Figure 2: Research Model

3 Methodology

3.1 Survey Development and Sample Characteristics

A cross sectional survey was developed by the research team leveraging validated privacy measures where possible and developing context-specific measures as needed (See Table 5 in the Appendices). Perceived control (4 items) was adapted from [7], and Privacy Media Coverage (1 item) was adapted from [30]. Perceived fairness (1 item), privacy controls awareness (2 items), disclosure comfort (6 items) and disclosure behavior (5 items) were self-developed based on the data types professional GenAI users share [1]. The survey was launched using Prolific panel services in October 2024. This paper focuses on a subset of the broader dataset, namely participants currently employed or self-employed. This allows us to explore disclosure of different data types in the professional context. Prior to analysis, all participants indicating they were not employed were removed from the sample, resulting a total sample of 813, to be used in qualitative analysis. This sample was then reduced further by removing respondents who indicated they 'never' utilize GenAI for professional purposes resulting in a survey sample of 714 respondents. This was an important step to accurately examine professional disclosure behaviors. The survey sample was 50.4% female, 47.6% male, and 2% non-binary. There was a broad age distribution including 25.2% aged 18-30, 34.2% aged 31-40, 25.6% aged 41-50, and the remaining 15% aged 51 and over. In terms of education, 12.9% had a high school diploma or less, 18.5% had some college education, 11.2% and 31.8% had an Associates or Bachelors degree respectively, and the remaining 25.6% had a Postgraduate level education. In terms of factors related to work, 51% held non-managerial roles, 38.8% held management roles, and 10.2% held executive level roles.

4 Analysis and Results

4.1 Descriptive Analysis

At the start of the survey, respondents were presented with a neutrally framed broad description of GenAI technologies. To qualify

for the survey, respondents must be active GenAI users, though their frequency of use could vary. Table 1 below presents the frequency of use across three different purposes. When using GenAI for professional purposes, 70.1% of respondents do so at least half of the time, and 13.9% do so on a daily basis. Table 2 summarizes the % of respondents uploading varying file types and requesting these file types as output from the Gen AI tools. Interestingly, a high number of respondents upload text documents (46%), images (40.5%), and spreadsheets (16%). These findings are interesting as these files may include data related to others, thereby creating networked privacy risks.

Table 1: Frequency of Use by Purpose

	Personal Use	Professional Use	Educational
Never	9 (1.3%)	n/a	237 (33.2%)
Infrequently	138 (19.3%)	200 (28%)	200 (28%)
About half of the time	172 (24.2%)	167 (23.4%)	119 (16.7%)
Several times a week	282 (39.5%)	234 (32.8%)	116 (16.2%)
Everyday	112 (15.7%)	113 (13.9%)	42 (5.9%)

Table 2: Input and Output File Types

Content Type	Input Use	Output Use
Text prompts	754 (93.4%)	752 (92.5%)
Text file	374 (46.0%)	384 (47.2%)
Code file	85 (10.5%)	119 (14.6%)
Spreadsheet	130 (16.0%)	127 (15.6%)
PowerPoint	75 (9.2%)	103 (12.7%)
Images	329 (40.5%)	350 (43.1%)
Video	66 (8.1%)	78 (9.6%)
Audio	76 (9.3%)	71 (8.7%)

4.2 Structural Equation Modelling Analysis

The first stage of analysis investigated if the data met the thresholds needed to conduct multivariate analysis [12]. All items met recommended kurtosis and skewness thresholds based on [17], and all variables had variance inflation factors (VIF) below 10 demonstrating that multicollinearity is not an issue in the data. Confirmatory factor analysis (CFA) was conducted in AMOS v28.0. The model demonstrated good fit in line with the fit statistics [12]: cmin/df: 3.711, CFI: .963, RMSEA: .062, SRMR: .039. The validity and reliability of all constructs was examined (see Table 4). Convergent validity requires all constructs that should converge to strongly correlate with each other [34] and is assessed by calculating the average variance extracted (AVE). As all variables had AVE scores above .50, convergent validity is achieved [8]. Discriminant validity requires items on one construct to be sufficiently different from items on other constructs [34]. Discriminant validity was tested by comparing the square root of the AVE with the inter-construct correlations [12]. As the square root of AVE was higher than inter-construct correlations, discriminant validity was achieved. Reliability was assessed by calculating the composite reliability (CR). With CR scores above .70, all constructs were reliable [28]. The standardized regression weights for all survey items are provided in Table 5.

4.3 Findings

The hypotheses were tested using Structural Equation Modeling (SEM) in AMOS with results outlined below in Table 3 and Figure 3. The model demonstrated strong fit above recommended fit thresholds [12]: cmin/df: 2.013, CFI: .992, RMSEA: .038, SRMR: .018. H1a proposed a positive relationship between perceived control and disclosure comfort. This was supported in the data (H1a: β : .161, $p < .01$). H1b proposed a positive relationship between perceived fairness and disclosure comfort. This was supported by the data (H1b: β : .330, $p < .01$). H2a proposed a negative relationship between privacy media coverage and disclosure comfort. This was not supported (H2a: β : .012, $p > .10$). In H2b, a positive relationship between GenAI privacy controls awareness and disclosure comfort was proposed. This relationship was supported (H2b β : .318, $p < .01$). H3 proposes that disclosure comfort will have a positive association with information disclosure. This was supported in the data (β : .599, $p < .01$). Several control variables were included. Education (β : .084, $p < .01$) and organizational GenAI policy (β : .065, $p < .05$) both had positive, significant relationships with disclosure. Higher education increased disclosure, whereas if respondents' organization has restrictions on how GenAI can be used, they engaged in less information disclosure. As shown in Figure 3, our model explained 38% of variance in disclosure comfort and 41.2% of variance in disclosure behaviors. Indirect relationships were explored using bootstrapping with 2,000 samples. The results of these posthoc tests revealed significant indirect effects, with perceived control (β : .096, $p < .01$), perceived fairness (β : .198, $p < .01$), and privacy controls awareness (β : .190, $p < .01$) having positive indirect effect on information disclosure.

Figure 3: Path Model Results

4.4 Additional Qualitative Thematic Analysis

At the end of the survey, respondents were presented with an optional open-ended question which asked "What is your biggest concern with Generative AI?". This question provides a broader picture of the primary concerns for users, which may guide future research endeavors. We analyzed and qualitatively coded a total of 813 responses (all employed/self-employed participants irrespective of their purposes of GenAI use) using NVivo software. We include respondents who were employed/self-employed but not utilizing GenAI for professional purposes as their broad concerns are still relevant. Two independent coders conducted the initial coding, identifying major themes and sub-themes. The coders then engaged

Table 3: Findings

Hypothesis	Finding	Supported
H1a Perceived Control (+) Comfort Disclosing	(.161)***	Yes
H1b Perceived Fairness (+) Comfort Disclosing	(.330)***	Yes
H2a GenAI Privacy Media Coverage (-) Comfort Disclosing	(.012) n.s.	No
H2b Awareness of Privacy Controls (+) Comfort Disclosing	(.318)***	Yes
H3 Comfort Disclosing (+) Disclosure	(.599)***	Yes

in detailed discussions to resolve disagreements and finalize a cohesive set of eleven key themes. The process involved three iterative rounds of re-coding responses to refine the codebook. In the final two rounds, the coders collaboratively reviewed each response to reach consensus. Given the iterative nature of the thematic coding, which included multiple rounds of review, we did not calculate an inter-rater reliability score [23]. We double-coded responses when participants mentioned multiple concerns. For example, in instances where a participant referred to data breaches, and job loss, their response was coded under "Security and Privacy" and "Job Replacement" themes. Consequently, for each theme, the total count and percentages may exceed the sum of the counts for its sub-themes. We categorized responses into eleven primary themes, outlined in Table 6, including Security and Privacy; Job Replacement; and Data Deception, among others. A key finding was that 34% (n=276) of participants expressed concerns about security and privacy. Of these, 20.41% (n=166) were worried about general privacy and security risks, while 14% (n=114) cited data breaches, leaks, or hacking. Only 1.48% (n=12) mentioned potential financial losses, such as scams and identity theft. Concerns about job displacement (18.20%, n=148) and data deception (14.39%, n=117) were also notable. Specifically, 16% (n=130) feared AI replacing jobs, while 3.32% (n=27) saw AI as a threat to creative fields. Participants highlighted issues like bias, misinformation, and deepfakes under data deception concerns. While participants may have been primed by the privacy-related questions in our survey, our measures were largely neutrally framed and privacy and cybersecurity were top concerns above bias, job loss and deception in industry research [18]. Thus, we argue these findings suggest that privacy and related issues such as deception are core concerns for users of GenAI tools. A complete breakdown of concerns is provided in Table 6.

5 Discussion

In this exploratory study, we investigate GenAI users' information disclosure in the professional context, and how privacy perceptions, knowledge and comfort shape these disclosure patterns. Our survey findings demonstrate the role privacy perceptions of control and fairness play in fostering a sense of comfort in disclosing different data types to GenAI tools. When GenAI users believe they are in control over how the data they disclose is shared and used, their comfort in disclosing data types increases. The finding complements research on the positive association between perceived control and privacy concerns [38] and perceived privacy in various contexts e.g. [10]. Perceived fairness also increases disclosure comfort. This finding ties back to the view that privacy is not an absolute right, and the importance of balancing privacy with GenAI tools' need

for data to train and improve their offerings [21]. Achieving a balance between users' belief that the use of data for model training is appropriate is important to maintain relationships [2], as if individuals believe data usage is unfair, they may express privacy concerns [19, 20] or lower disclosure comfort. Beyond the testing of privacy perceptions in this new technological context, our findings demonstrate that perceptions of control and fairness, not only impact the formation of privacy beliefs with negative (privacy concerns) and positive (perceived privacy) framing, but also shapes users' feelings of comfort in engaging with GenAI tools.

Our findings provide mixed results on privacy knowledge. Firstly, awareness of privacy media coverage did not significantly impact disclosure comfort. This finding contradicts studies, which found privacy media coverage increased privacy concerns related to health data [10], and social media [26]. It may be that participants had not engaged with these stories in depth or did not see a link between these stories and their GenAI usage. Indeed, research suggests that individuals only engage with privacy breach stories and consider their own vulnerability when they have a high degree of familiarity with the injured party [9]. Second, awareness of privacy controls increased disclosure comfort. When GenAI users are **not only aware** of the existence of these privacy settings but are **confident in their ability** to utilize these controls, they are more comfortable disclosing data. Qualitative studies exploring GenAI disclosure have found that most participants are not aware of these settings [16, 41]. Interestingly upon being informed, participants in both studies reacted differently. In [41], participants viewed these features as beneficial and expressed a desire to try them, whereas participants in [16] were unlikely to engage with these settings citing questions over their efficacy. This begs the question, is it the illusion of control this confidence in utilizing privacy controls creates, rather than the utilization of these tools, driving feelings of comfort? Worryingly, if it is the former, privacy controls awareness may not encourage behaviors which, in reality, improve networked privacy management at the individual user level. Lastly, disclosure comfort was positively related to disclosure, with individuals who feel comfortable disclosing engaging in higher disclosure. Furthermore, perceived control, perceived fairness, and privacy controls awareness had indirect effects on disclosure. These findings provide initial evidence of the role of privacy perceptions and knowledge in impacting disclosure in the professional GenAI context. In addition, respondents with higher education levels reported higher disclosure and if respondents' organization had restrictions on how GenAI could be used, they engaged in lower disclosure.

Our study makes several contributions. Research examining employees' use of GenAI, especially using a quantitative lens, remains scarce [14]. First, this study makes some steps towards enhancing

our understanding of **how employees use GenAI**, moving beyond the factors impacting if they adopt GenAI. Our study also answer calls for quantitative privacy research in the GenAI context [41]. Second, while privacy has emerged as a core issue in qualitative studies of professional users and non-users [37], this study is among the first to quantitatively focus on privacy in the critical professional context. Third, we operationalize a disclosure comfort variable and a novel approach to understanding the situational perceptions and knowledge variables of importance in this context and provide interesting insights on the importance of control, fairness, and privacy controls awareness in driving comfort levels. Lastly, we supplement these findings with a qualitative exploration of the primary concerns individuals hold regarding GenAI. Our findings also present practical implications to GenAI organizations and the organizations leveraging their solutions. In terms of the former, GenAI developers should highlight the controls GenAI users have over their data and ensure they are easy to find and utilize within the interface. Fairness perceptions can be strengthened through communicative efforts explaining how data is used, protected, and why. For organizations with employees leveraging GenAI, clear and concise acceptable use policies should be drawn up and communicated to staff in an effective manner. Our findings suggest that merely having restrictions on use can reduce disclosure and help with networked privacy management as a result. These policies can be supplemented with training on the privacy risks associated with use.

5.1 Limitations and Future Research Directions

This study has limitations which can be addressed through future research. First, the study relies on self-reported data at one point in time. While this approach provides valuable insights given the early status of GenAI, users' perceptions are likely to change over time. Future research can adopt longitudinal research designs [41] or utilize actual disclosure data. Second, the paper develops a parsimonious model, and thus may omit potentially impactful variables. There are other privacy co-variables researchers may be interested in such as trust and risk. Furthermore, as some variables were self-developed, researchers may want to engage in construct development exercises or the adaptation of existing variables to the GenAI situational context, or examine the role of privacy perceptions at broader levels such as general privacy beliefs and dispositions. Third and relatedly, there are other outcome variables which may be of interest. For instance, it would be interesting to delve deeper into disclosure behaviors to illuminate if individuals engage in privacy-protective behaviors [31] such as withholding or falsifying data. Qualitative research has provided some initial evidence of users attempting to protect data disclosed through redaction and falsification [16]. It would be interesting to quantitatively examine when individuals engage in privacy-protective behaviors. There is a need for experimental work. Future research could pursue an experimental approach to determine if exposure to real news stories impacts disclosure comfort and other important covariates, and to investigate what kinds of stories are more impactful in leading individual users to consider their own use behaviors and associated networked privacy risks. Research should also delve into if awareness of privacy controls and confidence in one's ability to use them translates into utilization.

6 Conclusion

GenAI has proliferated many facets of our personal and professional lives at an unprecedented pace. While these technologies offer many benefits for individuals and organizations, they foster networked privacy risks in the professional context, due to excessive data sharing by users, traditional security risks, and GenAI-specific memorization risks. This study demonstrates that users' privacy perceptions and knowledge shape their comfort disclosing, and ultimately their professional data disclosure. In order for organizations and their employees to leverage these technologies safely, a comprehensive education effort is required to ensure employees (i) understand the risks of their disclosure behaviors, (ii) are knowledgeable of appropriate use policies, and (iii) are capable of utilizing available privacy controls.

7 Appendices

Table 4 below outlines the composite reliability (CR) and Average variance extracted (AVE) for all latent variables. These scores meet acceptable guidelines for multivariate analysis [12].

Table 4: Reliability and Validity Findings

	CR	AVE
Perceived Control	0.869	0.772
Awareness of Privacy Controls	0.769	0.814
Comfort Disclosing to Gen AI	0.901	0.532
Disclosure Behaviors	0.819	0.689

The table 5 below outlines the wording for all survey items and their associated item loadings where appropriate. Most items have high loadings above the recommended threshold of .700, with the exception of a small number of items. However, as each of these loadings are over .600, they are acceptable given the sample size [12].

Table 6 summarizes participant's concerns about GenAI, categorized into various themes, sub-themes, example quotes, and frequency data.

Table 5: Questionnaire Items

Construct	Item	Wording	Loading
Perceived Control	CON1	I think I have control over what information about me is released by gen AI applications	.895
	CON2	I think I have control over what information about me is released by gen AI applications	.915
	CON3	I believe I have control over what information is collected by gen AI applications	.782
	CON4	I believe I can control my personal information provided to Gen AI apps	.720
Perceived Fairness	FAIR1	In general, how reasonable is it for GenAI applications to use people's private data for training its algorithm?	N/A
Privacy Media Coverage	MEDIA1	Over the last year, how often have you heard or read about the potential misuse of personal information by Gen AI applications?	N/A
Privacy Literacy	PLIT1	When using Gen AI, I know how to utilize privacy features e.g. turn off model training	.914
	PLIT2	When using Gen AI, I know how to control data collection e.g. turn off prompt memorization	.838
Disclosure Comfort	COMF1	When using Gen AI applications, how comfortable are you providing Personally identifiable information e.g name, address	.747
	COMF2	When using Gen AI applications, how comfortable are you providing Financial information e.g. credit score, credit card information, banking details	.788
	COMF3	When using Gen AI applications, how comfortable are you providing Health information relating to physical and mental health	.675
	COMF4	When using Gen AI applications, how comfortable are you providing Employee information including salary and other personal details	.752
	COMF5	When using Gen AI applications, how comfortable are you providing Customer information	.736
	COMF6	When using Gen AI applications, how comfortable are you providing Company information	.677
Disclosure Behavior	DIS1	When using AI for work purposes, how often do you upload Information about internal processes	.801
	DIS2	When using AI for work purposes, how often do you upload Non-public information about the company	.816
	DIS3	When using AI for work purposes, how often do you upload Employee names or information	.939
	DIS4	When using AI for work purposes, how often do you upload Customer names or information	.877
	DIS5	When using AI for work purposes, how often do you upload my colleagues' work for correction	.670

Table 6: Thematic Analysis of Generative AI Concerns

Theme	Subtheme	Example Quotation	Frequency (%)
Accuracy, Hallucinations, and Reliability		"The accuracy of information"	93 (11.44%)
AI misuse			89 (10.95%)
	General Misuse	"The wrong people will use it for bad things"	74 (9.10%)
	Cheating, Plagiarism, and Copyright	"People using it to cheat"	16 (1.97%)
Data Collection		"Data collection and profiling its users"	49 (6.03%)
Data Deception			117 (14.39%)
	Misinformation	"Misinformation being passed off as facts"	61 (7.50%)
	Bias	"Biases and fairness"	37 (4.55%)
	Deepfake	"Misuse of deepfake technology"	23 (2.83%)
	AI vs Human Output	"It will be hard to tell what is authentic and what is not"	18 (2.21%)
Dependence on AI		"People relying on it too much"	39 (4.80%)
Existential Risk			68 (8.36%)
	Sentient AI	"It will take over the world one day"	48 (5.90%)
	Owner's or Programmer's Manipulation	"An AI is only as positive or destructive as the person who programs it."	17 (2.09%)
	Human in the Loop	"Lapses in judgment/human touch"	4 (0.492%)
Job Replacement			148 (18.20%)
	Job Replacement by AI	"Being way too smart to destroy the job market"	130 (15.99%)
	Threat to Creative Field	"Being flooded with AI-related work in creative fields"	27 (3.32%)
Lack of AI Regulation			39 (4.80%)
	AI Restriction, Governance	"Governance over its usage"	16 (1.97%)
	Transparency, Accountability	"Not being able to figure out how they work"	15 (1.85%)
	Ethics, Morality	"Morality/ethics standards we have built our society on being compromised"	11 (1.35%)
Long Term Impact		"How it ends up being used in the long term"	20 (2.46%)
Security and Privacy			276 (33.95%)
	Overall Security and Privacy	"Data protection for users and customers of the Gen AI service"	166 (20.42%)
	Data Breach	"Data/privacy breach of my previous conversations, etc."	114 (14.02%)
	Financial Loss	"Leakage of private personal information, specifically things like social security number and financial information"	12 (1.48%)
Others			65 (8.00%)
	Environmental Impact	"Environmental effects"	5 (0.62%)
	Cost	"Becoming costly to use"	4 (0.49%)
	Lack of User Manual	"That sometimes I do not know how to use it."	4 (0.49%)
	Benefits of AI	"Looks positive and can be very helpful"	3 (0.37%)
	No Concern	"None so far"	47 (5.78%)
