Abstract

The use of artificial intelligence (AI) and voice user interfaces (VUIs) in hiring processes is a rapidly growing trend. Since the COVID-19 pandemic, an increasing number of companies have adopted automated systems for conducting job interviews. In traditional interview settings, research has shown that gendered interactions between the interviewer and the interviewee can influence performance and hiring decisions. Addressing this issue within the digital job-seeking context, our study investigates whether similar effects occur in interactions with LLM-based voice chatbots during mock job interviews. We conducted a study using two gendered AI interviewer conditions: a feminine AI voice and a masculine AI voice. The study examined how the AI interviewer's gender presentation influenced interviewees' lexical diversity, willingness to disclose personal information, and confidence levels. Preliminary findings indicate that gender stereotypes persist in interactions with AI chatbots, with participants associating stereotypical feminine traits with the feminine AI voice. Furthermore, participants reported a more positive overall interview experience with the feminine voice compared to the masculine voice.

CCS Concepts

• Human-centered computing → Interaction design; • Computing methodologies → Artificial intelligence.

1 Introduction

1.1 Background

The use of AI agents in job interviews has surged since the COVID-19 pandemic, with estimates suggesting that up to 86% of employers

now utilize technology-mediated interviews [4]. Prior research has demonstrated that the gender of the interviewer can significantly influence applicant behavior, both explicitly and implicitly [7]. For example, male interviewers with stronger implicit gender stereotypes tend to give lower evaluations to female applicants, which in turn negatively impacts the applicants' self-evaluation. Specifically, female applicants evaluated themselves as less hireable when male interviewers rated them poorly [7]. As job interviews serve as a critical gateway to employment—shaping individuals' social and economic positioning in the workplace—addressing these biases is essential to fostering equity in the workforce. Given that gender stereotypes often arise in traditional human-to-human job interviews, it is crucial to explore solutions that promote fairness in these high-stakes interactions. To examine whether these gender influences extend to AI-based interview systems, we developed an AI-driven voice chatbot designed to simulate a job interview environment. While prior research has extensively explored the gendered effects of voice assistants (VAs) [1, 3, 6], there is little to no research addressing the role of large language model (LLM)-based voice chatbots in the specific context of job interviews. Our voice chatbot was programmed to use commonly employed behavioral interview questions. To evaluate applicant performance, we analyzed three key metrics: the lexical complexity of responses, participants' willingness to disclose personal information, and their self-reported confidence levels. Additionally, we examined participants' perceptions of the AI interviewers by analyzing the attributes they associated with different gendered chatbots. This study aims to provide insights into designing a more equitable AI-mediated interview environment for all job seekers.

2 Related Work

2.1 Gender in Voice User Interfaces (VUIs)

In recent years, Voice User Interfaces (VUIs) have been increasingly adopted, particularly through voice assistants (VAs) from companies such as Google, Amazon, and Microsoft, which interact with users in their daily lives. OpenAI has also recently introduced voice capabilities for ChatGPT, enabling users to engage with a generative artificial intelligence (AI) agent in conversational interactions that extend beyond traditional chatbot functionality. The gendered aspects of voice agents have been widely examined in the literature, revealing that feminine VAs are often sexualized and described as submissive. Studies have shown that stereotypical femininity is frequently embedded in VAs to enhance usability and foster a sense of intimacy with users [6]. Another study highlights that men are more likely to exhibit biased behaviors toward feminine VAs, displaying more favorable non-verbal reactions during their interactions [9].

2.2 Gender Biases in Human-AI Interactions

Gender stereotypes have been shown to be carried over to humans' interactions with AI. One study highlights the presence of gender stereotypes in AI agents and the importance of eXplainable AI (XAI) in mitigating the individual's stereotypes [3]. Another study researched the preference for gendered AI bots, indicating that individuals are more likely to perceive female AI bots to be more human-like [1]. Participants preferred female bots over their male counterparts, indicating that female bots seemed more likely to consider their unique needs. The study further illuminates the harms that this preference towards female AI bots may adversely reinforce harmful gender stereotypes.

2.3 Human-AI Interactions in Job-seeking Activity

With the increased demand for efficient and reliable interview preparation tools, there has been research on utilizing AI and LLMs to create systems that simulate authentic interview scenarios. One study developed a virtual AI system that provides comments on the applicant's eye contact, head posture, and confidence [8]. Another research highlights the usage of virtual agents in interviewing systems to analyze the applicants' non-verbal features, such as their gaze, linguistic features, and biological features to predict their communication skills and self-efficacy skills. Through this, it highlights the importance of multimodal features in evaluating job interview performance [10].

3 Research Questions

While existing literature examines the effects of gender on job interviews and the use of large language models (LLMs) in developing virtual interview agents, there is limited research addressing the potential gendered impacts of LLM-based VAs when conducting job interviews. To bridge this gap, we have developed a web platform that incorporates an AI-powered voice chatbot designed to simulate behavioral job interview scenarios. Using this platform, we aim to investigate how different gender presentations (feminine and masculine) of AI voices influence participants' performance during mock job interviews. Specifically, we seek to examine the effects of gendered AI interviewers on participants' performance and perceptions by addressing the following research questions:

- **RQ1:** Does the perceived gender of an AI interviewer affect participants' formal language, sentence structure, and vocabulary?
- **RQ2:** Does the perceived gender of an AI interviewer impact a participant's willingness to share personal information?
- **RQ3:** Does the perceived gender of an AI interviewer affect the participant's perception of the AI's authority and competence?
- **RQ4:** Does the perceived gender of an AI interviewer affect the participant's self-reported confidence levels?

4 Interface Design

We developed a web-based voice chatbot using OpenAI's API, implemented in two distinct conditions: one with a feminine voice, "Nova," from OpenAI's text-to-speech (TTS) library, and the other

with a masculine voice, "Onyx," from the same library. The prompts and technical design were kept consistent across both conditions. The chatbot was programmed to ask users eight behavioral questions during the interview. To simulate a realistic conversation, the chatbot also responded to users' answers and asked appropriate follow-up questions. Users interacted with the chatbot by pressing a microphone icon on the screen to record their voice messages (Fig. 2 in appendix). These messages were transcribed by the system and displayed on the screen for clarity. The chatbot's text responses, generated by OpenAI's GPT-4 model, were converted into audio files using OpenAI's TTS functionality and played aloud after each user response.

4.1 Prompt Design

To generate the system prompts, we began by researching common behavioral questions typically asked in real job interviews. Since our goal was to simulate a general job interview environment rather than one specific to any industry, we compiled a list of questions focusing on the interviewee's personal traits and experiences. To establish the AI as a professional interviewer and simulate a conversational interview format, we provided the chatbot with the following prompt: *"You are an AI Interviewer that asks interview questions to the user. After the user gives an answer, provide a brief response and move on to the next question. If the user provides a short response, ask them to elaborate and request more information, including specific examples. If the user mentions particular work experiences or job positions, follow up with questions about those experiences to gather more detail. Use conversational responses to the user's answers to make the interaction feel like a natural conversation."* This prompt guided the chatbot in maintaining a professional yet conversational tone throughout the interview.

5 Methodology

We designed the experiment to explore how different gender presentations of AI interviewer voices influence participants' performance during mock job interviews and their attitudes toward the AI interviewers. The study employed a between-subjects design, with each participant interacting with only one condition of the chatbot. All sessions were conducted in person within a private, distraction-free environment, ensuring participants could engage with the AI interviewer uninterrupted. Researchers remained outside the interview setting during the study to maintain a controlled environment. To accommodate participants' diverse professional goals, we selected non-industry-specific behavioral questions and ensured all participants were asked the same set of questions.

5.1 Participants

Participants were recruited from undergraduate students at a liberal arts college in the United States using convenience sampling through email and text outreach. A total of 14 participants (N=14) completed the study. Of these, 10 identified as female, 3 as non-binary, and 1 as male. All participants were between the ages of 18 and 21. Participants were randomly assigned to one of the two gender conditions: 7 interviews were conducted using a feminine voice, and the remaining 7 were conducted using a masculine voice.

5.2 Questionnaire Design

5.2.1 Pre-Study Questionnaire. The pre-study questionnaire, consisting of 13 questions, assessed the participants' confidence levels in job interviews. We utilized the Multi-dimensional Job Interview Self-Efficacy scale (MJISE) introduced by Petruzzello et al. [11] to measure confidence levels specific to job interviews. Out of the five factors introduced by Petruzzello et al., we utilized the scales for the three factors: Self-promotion SE (S-P SE), Interview-related Anxiety Management SE (IAM SE), and Interaction SE (IN SE). The Interview Preparation SE (IP SE) and Logistical SE (LO SE) factors were excluded as our chatbot simulated an online interview environment, and was not targeting a specific industry. The full MJISE scale is available in the appendix (Fig. 3).

5.2.2 Post-Study Questionnaire. The post-study questionnaire consisted of 24 questions and assessed participants' confidence levels in job interviews after their interaction with the AI interviewer. The MJISE scale used in the pre-study questionnaire was also employed post-interview to evaluate changes in confidence levels. Additionally, a 5-point scale was included to assess participants' attitudes toward the AI interviewer and their evaluation of its competency. Competency was measured using metrics proposed by Mahmood et al., [9] which assess perceptions of agent characteristics alongside subjective measures of user experience and perceptions of AI. Subjective measures of user experience and perceptions of AI were assessed through participant ratings of the AI interviewer on human-likeness, warmth, and competence. Human-likeness was measured on the dimension of "Robotic – Human." Warmth was evaluated on the following dimensions: 1) Cold – Warm, 2) Unfriendly – Friendly, 3) Insincere – Sincere, and 4) Boastful – Modest. Competence was assessed on the following dimensions: 1) Unskillful – Skillful, 2) Impractical – Practical, and 3) Foolish – Intelligent. Open-ended questions were also included, prompting participants to reflect on their interview experience and to provide three adjectives to describe their interaction with the AI interviewer.

5.3 Protocol

All participants' interview with the AI interviewer was recorded and transcribed.

5.3.1 Task 1: Pre-Study Questionnaire. At the beginning of the study, participants completed a pre-study questionnaire to provide demographic information and assess their confidence levels. They were then introduced to the interface of our chatbot, which was presented as an AI interviewer from a mid-size firm called Horizon Partners, tasked with asking basic behavioral questions. Participants were also given instructions on how to record their responses. To eliminate bias during the interview, all participants were asked to participate under the androgynous pseudonym "Alex." Once the interface was prepared for the interview, participants were left alone with the chatbot to complete the session. This setup was designed to encourage honest responses and simulate a realistic online job interview environment.

5.3.2 Task 2: Mock Job Interview. The participants engaged in a 20 minute interview with the chatbot. The length of the interview varied for each participant, based on the length of their responses. The chatbot asked the following eight behavioral questions:

- (1) Tell me about yourself.
- (2) What are your strengths?
- (3) What are your weaknesses?
- (4) Tell me about a time you handled a challenging situation in the workplace, and what did you learn from it?
- (5) Describe a time when you had to learn something new. In what ways did you approach the learning process?
- (6) What is your typical way of dealing with conflict? Give me an example.
- (7) Give me examples of projects/tasks you started on your own. What was the end result?
- (8) Career-wise, where do you see yourself in five years?

Once the participant was done with the interview, the participant communicated with the researcher through Google Chat to inform that they were finished.

5.3.3 Task 3: Post-Study Questionnaire. After the participants finished their interviews, they were provided with a post-study questionnaire.

6 Data Analysis

To explore how different gender presentations (feminine or masculine) of AI interviewer voices influence participants' performance during mock job interviews and their attitudes toward AI interviewers, we analyzed the following: (i) the lexical diversity in participants' responses, (ii) the amount of personal information disclosed in their responses, (iii) their perceptions and attitudes toward the AI interviewer, measured through post-study questionnaire ratings and a thematic and sentiment analysis of open-ended responses, and (iv) changes in confidence levels before and after the interview. For our preliminary study, we employed an independent samples t-test to examine differences between the two chatbot conditions. Prior to analysis, we conducted a Shapiro-Wilk (S-W) test to assess normality and Levene's test to check for equal variance. While the datasets did not meet the normality assumption, the two conditions demonstrated equal variance both within and between groups. Consequently, we proceeded with the independent samples t-test to compare the two conditions in the subsequent analysis.

6.1 Lexical Diversity

As a measure to calculate the participants' formal language, sentence structure, and vocabulary in their interview responses, we chose to use the Type-Token Ratio [12]. The TTR ratio is a measure of lexical diversity that compares the number of unique words in a text to the total number of words. The transcription of the participants' interview responses were calculated using the TTR ratio. The TTR ratio was calculated in Python (version 3.12.6) using the Natural Language Toolkit (NLTK) Python libraries.

6.2 Disclosure of Personal Information

To assess whether participants were more likely to share personal information with a specific gender condition, we evaluated the

frequency of personal information disclosures. Personal information was defined as mentions of personal struggles, provision of identifying details, and expressions of emotional responses. Each instance was identified and coded by the researchers through a systematic review of the transcripts of participants' responses.

6.3 Perceptions towards AI Interviewer

In addition to evaluating participants' interview performance across different gender conditions, we analyzed their attitudes toward AI interviewers based on dimensions such as human-likeness, skillfulness, practicality, intelligence, warmth, friendliness, sincerity, and modesty. These attributes were measured using a 5-point scale in the post-study questionnaire. Alongside the quantitative measures, we conducted a thematic analysis [2] of the open-ended responses to identify key themes in participants' interactions with the AI interviewer. For the thematic analysis, initial codes were generated from a preliminary review and then were consolidated into broader categories based on the frequency of their occurrence. Additionally, the "three-word task" was analyzed using sentiment analysis, where the adjectives provided for each condition were assigned sentiment scores to compare perceptions across gender conditions.

6.4 Confidence Levels

For our fourth research question, we examined whether the gender of the AI interviewer impacts participants' confidence levels. Using responses from the MJISE scale, we calculated the difference in confidence levels before and after the interview. This analysis allowed us to identify specific areas where participants experienced changes in confidence as a result of completing the interview.

7 Results

7.1 RQ1: Does the perceived gender of an AI interviewer affect participants' formal language, sentence structure, and vocabulary?

Overall, we found that participants who interacted with the feminine voice condition exhibited higher lexical diversity in their responses. Specifically, participants in the feminine AI voice condition had a mean TTR score of 0.35, compared to a mean score of 0.30 for participants in the masculine AI voice condition. To assess the difference in lexical diversity, we conducted an independent samples t-test at a 0.05 significance level. The t-test revealed a significant difference in TTR, $t(12) = 2.78$, with a p-value of $p = 0.008$ (Table 1 in the appendix).

7.2 RQ2: Does the perceived gender of an AI interviewer impact a participant's willingness to share personal information?

On average, participants who interacted with the feminine AI voice shared personal information 7.57 times, while those who interacted with the masculine AI voice shared personal information 9.57 times. An independent sample t-test at a significance level of 0.05 revealed no significant differences between the two conditions, with the p-value of $p = 0.149$. Descriptive statistics can be found in Table 2 in the appendix.

Figure 1: Number of Positive, Neutral, Negative Words in Three Word Task

7.3 RQ3: Does the perceived gender of an AI interviewer affect the participant's perception of the AI's authority and competence?

7.3.1 Three Word Descriptions. When the participants were asked to describe their experience, the most commonly mentioned word in the masculine AI voice condition was "anxious". Other words such as "curious, confused, rewarding" were also mentioned. When calculating the sentiment score, we used the spaCy library for advanced Natural Language Processing (NLP) in Python. For participants who engaged with the masculine AI voice, the sentiment score showed to be slightly negative, resulting in -0.06. For the feminine AI voice condition, the most commonly mentioned word was "calm" and "prepared". Other words such as "thoughtful, interested, supportive" were also mentioned. The sentiment score for the feminine AI voice showed to be slightly positive, resulting in 0.29. Sentiment analysis revealed that participants who interacted with a feminine AI interviewer used more positive descriptions and adjectives to characterize their experiences than participants who interacted with the masculine AI interviewer. For a visual representation of the positive, neutral, and negative words used, refer to 1 Descriptive statistics for the TTR ratio can be found in Table 1.

7.3.2 Thematic Analysis on Open-ended Responses. Through our thematic analysis of the open-ended responses, we found that participants who interacted with the masculine AI voice more frequently commented that it felt less realistic, describing it as sounding more like a typical ChatGPT agent. In contrast, participants who engaged with the feminine AI voice noted that it was helpful to interact with the interviewer, with some describing the prompts as "super helpful" and praising it for providing "a really insightful compliment." Participants in both conditions, however, expressed that the interviewer seemed to take their answers for granted and did not provide sufficiently probing follow-up questions.

7.3.3 Participant Attitudes. Using the metrics from the post-study questionnaire, we evaluated participants' attitudes toward AI interviewers across the following scales: Human-likeness, Skillfulness, Practicality, Intelligence, Warmth, Friendliness, Sincerity, and Modesty. An independent samples t-test was conducted to compare these scales between participants who interacted with the masculine AI interviewer and those who interacted with the feminine AI

interviewer. A statistically significant difference was found at the 0.05 significance level when evaluating modesty. Participants rated the feminine AI interviewer ($M = 4.57$, $SD = 0.787$) as significantly more modest than the masculine AI interviewer ($M = 3.86$, $SD = 0.690$), with a p-value of $p=0.048$. This finding suggests that the feminine AI interviewer was perceived as more modest compared to its masculine counterpart.

7.3.4 Difference in Gender Perception. In the post-study questionnaire, participants were asked to rate the AI interviewer's voice gender on a 5-point scale (1 = feminine, 5 = masculine). All participants in the masculine voice condition rated the voice as a 5, resulting in an average score of 5. In contrast, participants in the feminine voice condition gave an average rating of 1.71. This suggests that while the masculinity of the AI voice was consistently recognized, femininity was perceived less uniformly in the feminine voice condition.

7.4 RQ4: Does the perceived gender of an AI interviewer affect the participant's self-reported confidence levels?

We were able to find differences in certain categories of the MJISE scale. The two confidence categories that showed significant difference before and after the interview was "Emphasize the most valuable work experiences you had" from the self-promotion SE (S-P SE) factor and "Maintain a calm approach" from the interview-related anxiety management SE (IAM SE) factor. Using the independent samples t-test, with a p-value of $p=0.048$ we identified that participants who were interviewed by the masculine AI interviewer had a decrease in confidence ($M=-0.14$, $SD=0.690$) when it came to "[emphasizing] the most valuable work experiences you had" whereas the participants who were interviewed by the feminine AI interviewer had an increase in confidence ($M=0.57$, $SD=0.787$). For "maintaining a calm approach", with a p-value of $p=0.041$, we identified that participants who were interviewed by the masculine AI interviewer had an increase in confidence ($M=0.14$, $SD=0.900$) whereas the participants who were interviewed by the feminine AI interviewer had a decrease in confidence ($M=-.086$, $SD=1.069$). There were no significant differences for the other characteristics.

8 Discussion and Limitations

The analysis of participant responses revealed that feminine AI voices elicited higher lexical diversity and more positive sentiment in interaction descriptors (RQ1 & RQ3). It was also shown that participants' existing gender biases [5] were projected to AI interviewers, as participants deemed the feminine AI interviewer to be more modest compared to its masculine counterpart (RQ3). The study's results highlight a notable impact on participants' confidence levels based on the AI interviewer's gender. Participants interacting with masculine voices reported decreased confidence in self-promotion but an increased ability to maintain composure. Conversely, feminine voices bolstered self-promotion confidence but posed challenges for maintaining a calm approach (RQ4). Our research is significant as it is among the first to examine the impact of a gendered LLM-based voice chatbot in job interview settings. Unlike previous studies focused on the gender of voice user interfaces

in isolation [6, 9], this research situates gendered voice user interfaces within job interview settings. By developing a voice chatbot that simulates a job interview environment, we provide valuable insights into the future of AI-powered job interviews while critically analyzing how participants' behavior differ based on the gender presentation of the AI voice assistant. As automated interview systems become increasingly prevalent, ensuring their neutrality and inclusivity is essential to prevent the reinforcement of systemic biases in the workforce. Our study contributes to this effort by offering actionable insights for designing AI tools that is equitable to all job seekers.

Our study's sample size ($N=14$) was relatively small and had a skewed distribution of the participants identifying mostly as female, limiting the generalizability of findings. Moreover, the use of only two voice conditions (feminine and masculine) does not account for the potential impact of androgynous or culturally neutral voices. OpenAI's TTS may have pre-programmed biases which may also have influenced participants' perceptions, necessitating further exploration of diverse voice datasets and synthesis techniques. Future work should expand on these findings by incorporating a larger, more diverse sample and testing additional voice conditions. Incorporating multimodal interaction elements, such as facial expressions or body language, could provide a more holistic understanding of gendered effects in AI-mediated interviews. Additionally, longitudinal studies examining how repeated interactions with gendered AI voices shape user behavior and confidence over time would be valuable.

9 Conclusion

We present findings from a study that examined two gendered AI interviewer conditions: a feminine AI voice and a masculine AI voice. The study explored how the AI interviewer's gender presentation influenced interviewees' lexical diversity, willingness to disclose personal information, perception of AI interviewer, and confidence levels. Overall, our findings suggest that gender stereotypes persist when interacting with AI chatbots and the different gendered conditions significantly impact participants' confidence levels in mock job interview settings.

Acknowledgments

We would like to thank our professor, Dr. Orit Shaer for her guidance in our project. We would also like to thank our teaching fellows, Zoe Mitchell and Mary Calabro, as well as our teaching assistant and Ada Wang for their support and assistance.

A Appendix

A.1 Voice Chatbot Interface

A.2 Prompts

You are an AI Interviewer, that asks interview questions to the user. When the user gives them their name, start by asking all of the following questions: Tell me about yourself. What are your strengths? What are your weaknesses? Tell me about a time you handled a challenging situation in the workplace, and what did you learn from it? Describe a time when you had to learn something new. In what ways did you approach the learning process? What is your typical way of dealing with conflict? Give me an example. Give me examples of projects/tasks you started on your own. What was the end result? Career-wise, where do you see yourself in five years? Each question should be asked after the user’s response. After the user gives an answer, give a brief response and move on to the next question. If the user gives a short response, ask to elaborate on more information and ask follow up questions for specific examples. If the user mentions specific work experience or job positions, ask about their experiences and follow up for more detail. Give conversational responses to the user’s answers when asking questions to make it feel like a conversation.

A.3 Survey Questions

A.3.1 Pre-Study Questionnaire. Q1-Q2

Q1 How would you describe yourself?

- (1) Male
- (2) Female
- (3) Non-binary / third gender

(4) Other

Q2 In relation to the job interview, how confident are you that you could... (Likert scale)

- (1) Convey a professional image
- (2) Emphasize the most valuable work experiences you had
- (3) Emphasize your work experiences and job-related skills
- (4) Elicit the interviewer’s interest in deeming you are suitable for the job
- (5) Stay calm
- (6) Manage the interview-related anxiety
- (7) Maintain a calm approach
- (8) Keep good self-control
- (9) Answer properly to tricky questions
- (10) Answer readily to unexpected questions
- (11) Handle a probing interview
- (12) Handle proper questions you were not prepared for

A.3.2 Post-Study Questionnaire. Q1-Q8

Q1 How would you describe yourself?

- (1) Male
- (2) Female
- (3) Non-binary / third gender
- (4) Other

Q2 In relation to the job interview, how confident are you that you could... (Likert scale)

- (1) Convey a professional image
- (2) Emphasize the most valuable work experiences you had
- (3) Emphasize your work experiences and job-related skills
- (4) Elicit the interviewer’s interest in deeming you are suitable for the job
- (5) Stay calm
- (6) Manage the interview-related anxiety
- (7) Maintain a calm approach
- (8) Keep good self-control
- (9) Answer properly to tricky questions
- (10) Answer readily to unexpected questions
- (11) Handle a probing interview
- (12) Handle proper questions you were not prepared for

Q3 List three words that comes to mind after taking the interview.
